3.1 Curves in \mathbb{P}^2

Curves in \mathbb{P}^2 are defined by homogeneous irreducible polynomials f : $C = V(f)$.

e.g., the line containing a pair of points $(p, q) \in \mathbb{P}^2$ is the set of points $up + vq$ for $(u, v) \neq (0, 0)$. It's equation $Ax = 0$ is obtained by solving $Ap = 0, Aq = 0$. (Think of $A = (a, b, c)$, $p = (x_1, y_1, z_1)$, $q = (x_2, y_2, z_2)$. Then $ax_1 + by_1 + cz_1 = 0$, $ax_2 + by_2 + cz_2 = 0$. Then $\begin{bmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$. i.e.,

$[a, b, c]$ is the kernel of the 2×3 matrix, which has rank 2.)

The restriction of a homogeneous polynomial $f(x, y, z)$ to a line $\ell = \{up + vq\}$ is obtained by substitution $f(up + vq)$. This is a homogeneous polynomial in u, v of degree $= \deg(f)$. Over \mathbb{C} , any such polynomial can be factored into linear factors $(up_i + vq_i)$. These are the points of ℓ (not necessarily distinct) that lie on $V(f)$. Thus, a plane polynomial curve of degree d meets a line in d points, counted with multiplicity.

Let f be a homogeneous polynomial of degree d in x_1, x_2, x_3 , and let $C = V(f)$. Let f_i denote $\frac{\partial f}{\partial x_i}$ and let $f_{ij} = \frac{\partial^2 f}{\partial x_i \partial x_j}$. Then the Hessian Matrix is the 3×3 symmetric matrix

$$H(f) = \left(\frac{\partial^2 f}{\partial x_i \partial x_j} \right)_{ij}.$$

Proposition (Euler's Formula). *Let f , $d = \deg(f)$, f_i be as above. Then $\sum_{i=1}^3 f_i x_i = f \deg(f)$.*

Proof. Check it for monomials, since it's additive. (CHECK NOT INCLUDED) \square

This works for polynomials in n variables.

Now consider the Taylor expansion of the restriction of f to $\ell = \{up + vq\}$. Setting $u = 1$ ($v = 0$ is p , so looking near the point p):

$$f(p + vq) = f(p) + \left(\sum f_i(p) q_i \right) v + \frac{1}{2} \left(\sum f_{ij} q_i q_j \right) v^2 + \mathcal{O}(v^3)$$

with $q = (q_1, q_2, \dots)$.

Proposition. 1. *If p is a point of C , then $f(p) = 0$.*

2. *Suppose $p \in C$, and $f_i(p)$ are not all 0. Then the equation of the tangent line T to C at p is $\sum f_i(p) q_i = 0$.*

3. *Let h be the Hessian of f at p . Then $\det h = 0$ iff p is a flex point C (i.e., a restriction of f to the tangent line at p has a zero of order ≥ 3 at p).*

Proof. 1. By definition.

2. Tangent line: if the restriction of f to T has at least a second order 0 (by definition). So looking at the coefficient of v , this is clear.

3. Exercise: Check that the restriction of the quadratic term to the tangent line is 0 iff $\det h = 0$. \square

Definition 1. If all the f_i vanish at p , then p is called a *singular* point of $C = V(f)$. Otherwise, say that C is *non-singular* at p . Say that C is a *non-singular curve* if it has no singular points.

3.1.1 Nonsingular curves

e.g. 1, an irreducible conic is always non-singular

Proof. Convert to $x^2 - yz = 0$. $f_x = 2x$, $f_y = -z$, $f_z = -y$. Since $(x, y, z) \in \mathbb{P}^2$, not all these can be zero, so it's nonsingular \square

e.g. 2, An irreducible plane cubic can have at most one singular point (exercise)

e.g. 3, The curve $x^d + y^d + z^d = 0$ is non-singular (smooth) for $d \geq 1$. (Fermat polynomial of degree d).

The partial derivatives are dx^{d-1} , dy^{d-1} , dz^{d-1} , not all zero (in \mathbb{P}^2)

e.g. 4, The curve $x^3 + y^2 - xyz = 0$ is singular at the point $(0 : 0 : 1)$.

Proposition. For most values of the coefficients of a polynomial of degree d , the curve $C = V(f) \subseteq \mathbb{P}^2$ is smooth.

Proof. See two proofs, each of which depends on some theorem which will be proved later.

Setup: Order the monomials of degree d in x, y, z arbitrarily m_1, m_2, \dots, m_N . (Note: $N = \binom{d+k-1}{k-1}$ for k variables.)

An arbitrary polynomial of degree d is a linear combination of the monomials m_ν with some coefficients z_ν . Think of z_ν as variables and let

$$F = \sum_{\nu=1}^N z_\nu m_\nu \in \mathbb{C}[x, y, z, \{z_\nu\}].$$

Then $F = 0$ defines a subvariety \mathcal{C} of the product $\mathbb{P}^2 \times Z$, where Z is \mathbb{A}^N with coordinates z_ν .

The fiber $\mathcal{C}^0 = \pi^{-1}(z^0)$ of \mathcal{C} over a point $z^0 \in Z$ is the curve whose equation is the polynomial obtained.

by substituting z_ν^0 for z_ν . The 3 partial derivatives F_x, F_y, F_z are polynomials in $x, y, z, \{z_\nu\}$ linear in z_ν and homogeneous of degree $d-1$ in x, y, z . They define some subvariety of $\mathbb{P}^2 \times Z$. Let S be the variety $\{F_1 = F_2 = F_3 = 0\}$. Note that $S \subset \mathcal{C}$ (by Euler).

The fiber \mathcal{C}^0 over a point z^0 of Z is smooth if and only if \mathcal{C}^0 doesn't meet S .

We can construct $\Sigma = \pi(S)$ the image of S via a polynomial $\mathbb{P}^2 \times Z \rightarrow Z$. Later we'll prove that the image of the projection of any Zariski closed subvariety of $\mathbb{P}^2 \times Z$ to Z is also Zariski closed.

So the set Σ is closed in the affine space Z . But Σ is not all of Z (because the Fermat curve is smooth). So $\Sigma \subset Z$ is a proper closed subvariety. So the set of z^0 for which \mathcal{C}^0 is smooth is a Zariski open subset of \mathbb{A}^N . \square
