Recall:

If I is an ideal of A, then $\operatorname{rad} I = \{x \in A \mid x^n \in I, \text{ some } n > 0\}$ $V(I) = V(\operatorname{rad} I)$ $V(I) \supset V(J) \iff I \subset \operatorname{rad} J$ irreducible closed set $C: C \neq C_1 \cup C_2, C_i < C$.

Proposition. I an ideal, V(I) irreducible if f rad I is prime ideal

Theorem. Let A be a finite-type noetherian ring, I an ideal. Then rad I is the intersection of a finite number of prime ideals rad $I = P_1 \cap \cdots \cap P_k$. Then we can organize $P_i \not\subset P_j$ for $i \neq j$. Then we have that $V(I) = V(P_1) \cup \cdots \cup V(P_k)$; V(I) is a finite union of irreducible closed sets.

18.721 Notes

 $\operatorname{spec} A = \{ \text{maximal ideals} \}$ $V(I) = \{ \mathcal{M} \text{ that contains } I \}$

I an ideal. Then $\bar{A} = A/I$.

$$A \to \overline{A}$$

$$I \leadsto (\overline{0})$$

$$rad I \quad rad(\overline{0})$$

$$= nitradical$$

$$= \{x \mid x^n = 0\}$$

The following are equivalent:

- rad $I = P_1 \cap \cdots \cap P_k$
- $\operatorname{rad}(\bar{0}) = \bar{P}_1 \cap \cdots \cap \bar{P}_k$

(in \bar{A}) also prime ideals

Proof. Suppose the theorem is false for some A and some I. Let $S = \{\text{ideals } J \text{ of } A \text{ such that rad } J \text{ is not a finite i} By hypothesis, <math>S \neq \emptyset$. Then there exists a maximal element I in S. Then rad I not a finite intersection of prime ideals, but every larger ideal is a finite intersection of prime ideals. *Note*:

- $I = \operatorname{rad} I$
- I is not a prime ideal

Then there exist ideals K, L, $K \not\subset I$, $L \not\subset I$, but $KL \subset I$. Replace K by K+I, L by L+I. Then we have

$$(K+I)(L+I) \subset KL + KI + IL + II \subset I.$$

(so it's ok to do these replacements).

Now K, L > I. Replace K and L with their radicals.

$$(\operatorname{rad} K)(\operatorname{rad} L) \subset \operatorname{rad}(KL) \subset \operatorname{rad} I = I$$

(so it's ok to these replacements.)

We have

$$\operatorname{rad} K = P_1 \cap \cdots \cap P_r$$
$$\operatorname{rad} L = Q_1 \cap \cdots \cap Q_s$$

. . .

We made a mistake somewhere. (Supposed to replace I by a zero ideal?) The version on the web is probably correct. Let's skip this for now.

Finite Group Action

Let B be a finite type domain, G the finite group of automorphisms of B. Let $A = B^G$.

Theorem. • A is a finite type domain

- G operates on spec B = Y
- Y maps to spec A = X. $Y \to X$ is surjective, and the fibers are the G-orbits in Y

Example. $B = \mathbb{C}[x,y], \ \sigma(x) = -x, \ \sigma(y) = -y.$ Then $\langle \sigma \rangle$ is a group of order 2.

The invariant functions are $u = x^2$, $v = y^2$, and w = xy. It's not hard to see that every invariant function can be written as some combination of these.

$$A = B^G = \mathbb{C}[u, v, w]/(w^2 - uv)$$

Then spec A = X = locus of $w^2 = uv$ in $\mathbb{A}^3_{u,v,w}$. This is a double cone in 3-space.

Proof. A finite type domain:

Take $\beta \in B$, orbit $\{b_1 = \beta, \dots, b_r\}$. Let $p(x) = (x - b_1) \cdots (x - b_r) = x^r - s_1(b)x^{r-1} + \cdots \pm s_r(b)$. We have that β is a root of p(x). Since the $s_i(b)$ are symmetric functions, $s_i(b) \in B^G = A$.

Since B is a finite type domain, say B is generated as an algebra by β_1, \ldots, β_m . Then each β_i is a root of the polynomial, coefficients in A.

Let $A_0 = \mathbb{C}$ -algebra generated by these roots. Then A_0 is a finite-type domain contained in B. Every element in B is a polynomial in β_1, \ldots, β_m .

If a polynomial with β_i as a root has degree d_i , then we only need monomials in β_i with degree $\leq d_i$. There are only a finite number of monomials in β_i of degree $\leq d_i$. Then B is spanned as an A_0 -module by these monomials. Thus, B is a finite A_0 -module.

 $A_0 \subset A \subset B$. Since A_0 is a finite-type domain, A_0 is noetherian. B is a finite-type A_0 -module. A is a submodule. Therefore, A is a finite-type A_0 module. Thus, A is a finite-type algebra. \square
