## 2.1 Affine varieties

**Definition 1.** An affine variety is the set of solutions to a system of polynomial equations

$$f_1(x) = f_2(x) = \dots = f_r(x) = 0$$

18.721 Notes

for  $f_1, \ldots, f_r \in \mathbb{C}[x_1, \ldots, x_n]$ . (x is shorthand for  $(x_1, x_2, \ldots, x_n)$ .)

Alternatively, it's V(I) for some  $I = (f_1, \ldots, f_r) \subset \mathbb{C}[x_1, \ldots, x_n]$ .

e.g., point:  $(x_0, y_0) = (x - x_0, y - y_0)$ 

line: all (x, y) for which ax + by + c = 0

conic: locus of complex zeros of a quadratic equation in two variables q(x,y)=0

cubic: locus of complex zeros of a cubic polynomial

Classification of these depends on what coordinate changes one allows. If we allow arbitrary invertible linear operators and translations, any line can be converted to x = 0. Any conic can be converted to either  $x^2 - y^2 - 1 = 0$  or  $x^2 - y = 0$ , by completing the square.

Zariski topology on an affine variety  $(V(I_0)) = X \subset \mathbb{A}^n$  is just subspace topology induced from Zariski topology on  $\mathbb{A}^n$  (i.e., closed sets of X are just all the y = V(I) which are contained in X). Note:  $V(0) = \mathbb{A}^n$  so  $V(0) \cap X = X$ . Check:

$$V(1) = \emptyset$$

$$\bigcap_{\alpha \in S} V(I_{\alpha}) = V\left(\bigcup_{\alpha \in S} I_{\alpha}\right)$$

$$= V\left(\sum_{\alpha \in S} I_{\alpha}\right)$$

(arbitrary intersection of closed sets is closed)

$$V(I) \cup V(J) = V(I \cap J)$$

(To see, consider a point  $p \in V(I \cap J)$ ,  $p \notin V(I)$ , show that  $p \in V(J)$ )

## 2.2 Projective Plane $\mathbb{P}^2$

Recall

$$\mathbb{P}^2 = \{(x:y:z) \in \mathbb{A}^3 \setminus \{0,0,0\}\} / (x:y:z) \sim (\lambda x:\lambda y:\lambda:z) \qquad (\lambda \neq 0)$$

(lines through origin in  $\mathbb{A}^3$  or  $\mathbb{C}^3$ )

A line in  $\mathbb{P}^2$  is given by an equation ax + by + cz = 0 as long as  $(a, b, c) \neq (0, 0, 0)$ . Note that (a, b, c) and  $(\lambda a, \lambda b, \lambda c)$  give the same line for  $\lambda \neq 0$ . So the set of lines forms another projective plane (dual projective plane  $\tilde{\mathbb{P}}$ ). This equation ax + by + cz = 0 exhibits the duality between points and lines.

**Lemma.** A pair of distinct lines contains exactly one point in common, and a pair of distinct points lie on exactly one line.

Recall that we had  $\mathbb{A}^2 \to \mathbb{P}^2$ ,  $(x,y) \mapsto (x:y:1)$ . Bijection between  $\mathbb{A}^2$  and  $U_z := \mathbb{P}^2 \setminus \{z=0\}$  (since  $(x:y:z) \mapsto \left(\frac{x}{z}, \frac{y}{z}\right)$  if  $z \neq 0$ ). Similarly we have  $U_x$  and  $U_x$  also in bijection with  $\mathbb{A}^2$ . Then  $U_x \cup U_y \cup U_z = \mathbb{P}^2$ . This is a cover, and is called the standard affine open covering of  $\mathbb{P}^2$ .

Note that  $U_x \cap U_y \subseteq U_x$  (this is  $\{(x:y:z) | x \neq 0, y \neq 0\} \subset \{(x:y:z) | x \neq 0\}$ ) is the set  $\{y \neq 0\} = D(y)$ . So its open in the Zariski topology.  $U_x \cap U_y \subseteq U_y$  is also open:  $V \subset \mathbb{P}^2$  is open iff all its intersections with the standard affines (standard affine open covers) are open (in the standard affines).

This is the same topology as the other version of the Zariski topology on  $\mathbb{P}^2$  by taking V(f), f homogeneous polynomial in  $\mathbb{C}[x,y,z]$ . to be a closed set in  $\mathbb{P}^2$ , and then take arbitrary intersections and finite unions. (same as quotient topology on  $\mathbb{A}^3 \setminus \{0\}$ )

Note: Since Zariski topology  $\subseteq$  classical/complex/Euclidean topology (all open sets in Zariski are open in classical)

This means we can define a classical topology as well on  $\mathbb{P}^2$ . It makes  $\mathbb{P}^2$  into a compact Hausdorff space.

*Proof.* Compact: Let  $C_z \subseteq U_z$  be the set of (u, v, 1) such that  $|u| \le 1$ ,  $|v| \le 1$  and similarly  $C_x$  and  $C_y$ . It's clear that  $C_x$ ,  $C_y$ ,  $C_z$  are compact (also closed subspaces of  $\mathbb{P}^2$  in the complex topology). Since  $\mathbb{P}^2 = C_x \cup C_y \cup C_z$ ,  $\mathbb{P}^2$  is compact.

## 2.3 Change of coordinates in $\mathbb{P}^2$

Four special points determine coordinates in  $\mathbb{P}^2$ :

$$e_1 = (1:0:0)$$
  $e_2 = (0:1:0)$   $e_3 = (0:0:1)$   $\epsilon = (1:1:1)$ 

Think of these as column vectors.

Change of coordinates is described by a  $3 \times 3$  invertible matrix P.

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = P \begin{bmatrix} x' \\ y' \\ z' \end{bmatrix}$$

(x is old, x' is new)

if the matrix is a scalar (diagonal) matrix, then it doesn't affect any coordinate change. Similarly, the coordinate changes corresponding to P and sP are the same.

If A = (a, b, c) and  $\ell$  is the line ax + by + cz = 0, AX = 0, then A(PX') = 0 or AP(X') = 0, so the equation for  $\ell$  in the new coordinates is AP.

**Proposition.** Let  $p_1$ ,  $p_2$ ,  $q_3$ , q be four points in  $\mathbb{P}^2$ , now three collinear. Then  $\exists!$  change of coordinates PX' = X such that  $X = p_1, p_2, p_3, q$  because  $X' = e_1, e_2, e_3, \epsilon$ .

*Proof.*  $p_1, p_2, p_3$  are linearly independent vectors in  $\mathbb{C}^3$ . So  $\exists$  transformation P such that  $Pp_i = e_i$ . Now q is non-collinear with  $p_1, p_2, p_3$ ; all of its coordinates are non-zero. Then scale each coordinate to take q to  $\epsilon$  (modifies P). This doesn't affect  $e_1, e_2, e_3$ .

Conics we had  $x^2 - y^2 - 1 = 0$  and  $x^2 - y = 0$  in  $\mathbb{A}^2$ . In  $\mathbb{P}^2$ , these become  $x^2 - y^2 - z^2 = 0$  and  $x^2 - yz = 0$ . We can transform the first into the second by doing  $x^2 - y^2 = z^2$ ,  $(x - y)(x + y) = z^2$ , coordinate change to  $x'y' = z'^2$ .
