B finite type, G operator(?)

$$A = B^G$$

Showed A finite type

 $Y = \operatorname{spec} B$

 $X = \operatorname{spec} A$

 $X \leftrightarrow \{G \text{ orbits in } Y\}$

 $G \times B \to B$

 $\sigma, b \leadsto \sigma(b)$

(left) $\sigma \tau(b)$: first τ , then σ

Then G operates on the right on Y.

 $q \in Y$, σ sends $q \to q^{\sigma}$

 $q^{\sigma\tau}$: first σ , then τ

View

$$y \leftrightarrow \{\text{homomorphisms } B \to \mathbb{C}\}$$

 $q \leftrightarrow \pi_q : B \to \mathbb{C}$
 $\leftrightarrow \{\text{max ideals of } B\}$
 $q \leftrightarrow m_q$

18.721 Notes

Operation on Y:

$$B \xrightarrow{\sigma} B$$

$$\downarrow^{\pi}$$

$$\mathbb{C}$$

$$\pi_q \circ \sigma(b) = \pi_q(\sigma b)$$

Define q^{σ} = that point such that $\pi_{q^{\sigma}} = \pi_q \circ \sigma$.

Operation on max ideals:

$$\mathcal{M}_{q^{\sigma}} = \sigma^{-1} \mathcal{M}_q$$

$$Y \to X$$
?

For any $p \in X$,

$$B \xrightarrow{\pi \circ p} \mathbb{C}$$

 $Y \to X$ sends $q \leadsto r$

$$B \xrightarrow{\sigma} B \xrightarrow{\pi_q} \mathbb{C}$$

$$A \xrightarrow{\text{id}} A \xrightarrow{\pi_p} \mathbb{C}$$

Therefore, G-orbits in Y map to points of X.

We want to show that different orbits $\{q_1, \ldots, q_r\} \neq \{q'_1, \ldots, q'_s\}$ in Y map to different points p, p' in X.

Proof. Plan: Find an element $a \in A$ such that a = 0 on orbit $\{q_i\}$, $\pi_q(a) = 0$, $a \neq 0$ on orbit $\{q'_j\}$. Then $\pi_{q'_j}(a) \neq 0$. This would give us that $a \in \mathcal{M}_{q_i}$ (same as $\in \mathcal{M}_p$) and $a \notin \mathcal{M}_{q'_j}$ (same as $\notin \mathcal{M}_{p'}$).

In B, choose $b \in \mathcal{M}_{q_1}$ (then) such that $b \notin \mathcal{M}_{q'_i}$ for all $j = 1, \ldots, s$. (Note: $b(q) := \pi_q(b)$.)

Diversion: Suppose
$$B = \mathbb{C}[x_1, \dots, x_n]/(f_1, \dots, f_k)$$
. b represented by the polynomial $p(x_1, \dots, x_n)$. spec $B \approx V(f_1, \dots, f_k)$ in \mathbb{C}^n . spec $B = (\max ideals) = (homomorphisms $B \to \mathbb{C}) = (V(I) \text{ if } B = \mathbb{C}[x]/I)$$

We can do this. (Think about choosing (hyper-?)planes that do not pass through finite sets of points.)

Let $a = \prod_{\sigma \in G} \sigma(b)$. a is invariant. a = 0 on q_1 because b divides a in B (since some $\sigma \in G$ is the

identity). Therefore a = 0 on the orbit (q_1) . $a \neq 0$ on q'_1 .

 $\sigma(b)$ evaluated at q_1' is $\pi_{q_1'}(\sigma b) = \pi_{q_1'}(b) = b$ evaluated at ${q_1'}^{\sigma}$. Therefore, $a \neq 0$ on the orbit.

11.1 Localization

Note: we always assume that the rings are domains and assume (whenever possible) that they're finite type algebras.

Definition. A multiplicative system S in a domain A is a subset of A satisfying

- $1 \in S$
- $0 \notin S$
- if $s, t \in S$, then $st \in S$

Definition. The elements of S serve as denominators in the ring of fractions

$$A_S := \left\{ \frac{a}{s} \,\middle|\, s \in S, a \in A \right\} / \sim$$

where $\frac{a}{s} \sim \frac{b}{t}$ if at = bs

$$A \hookrightarrow A_S$$

 $a \leadsto a/1$

Example. $S = \{1, s, s^2, \ldots\}, \ s \neq 0. \ A_S = A[s^{-1}] = A[y]/(sy - 1)$

Example. $S = A - \{0\}, A_S = fraction field$

Example. P a prime ideal of A, $S = A - P = \{s \mid s \notin P\}$. Then $s \notin P$, $t \notin P \implies st \notin P$. Then A_S is the localization of A at P. This is (perversely) denoted A_P .

18.721 Notes

If $A \subset B$ a subring, then we can relate ideals of A and B: Extended ideal: I^e

I ideal of A

IB = ideal of B generated by $\{I\}$

The elements are

$$\sum_{\text{finite}} x_i b_i \quad , \ x_i \in I, \ b_i \in B$$

Contracted ideal: J^c : For J an ideal of B, $(J \cap A) = ideal$ of A

$$(I^e)^c \supset I$$

$$(J^c)^e \subset J$$

For $A \subset B = A_S$:

$$I^e = IA_s = \{x/s \mid x \in I, \ s \in S\} / \sim$$

 $J^c=J\cap A.$ If $y/s\in J,$ then $y\in J\cap A=J^c.$ Therefore, $y/s\in (J^c)^e.$ Thus, $J\subset (J^c)^e,$ so $J=(J^c)^e.$

Corollary. If A noetherian, then A_S noetherian

Proof. Take an increasing sequence $J_1 \subset J_2 \subset \cdots$ of ideals in A_S . Let $I_{\nu} = J_{\nu} \cap A$. Then $I_1 \subset I_2 \subset \cdots$. Since A is noetherian, this is eventually constant. Therefore $I_{\nu}^e = (J_{\nu}^c)^e$ eventually constant. Thus A_S is noetherian.
